TITLE: High speed data compression and decompression apparatus and method

CLAIMS:

- 5. The <u>compression</u> apparatus of claim 2 in which said searching means includes <u>hash</u> function generation means responsive to said string code signals and to said data character signals for <u>hashing</u> a data character signal with a code signal to provide a <u>hash</u> signal, said <u>hash</u> signal providing a potentional <u>address</u> signal for <u>accessing said</u> memory means.
- 6. The <u>compression</u> apparatus of claim 5 in which said <u>hash</u> function generation means comprises means for providing a predetermined number of <u>hash</u> signals in response to a code signal and a character signal, said predetermined number of <u>hash</u> signals providing potential address signals for accessing said memory means.
- 7. The <u>compression</u> apparatus of claim 6 further including means for determining if all of said predetermined number of <u>hash</u> signals are unsuitable as <u>address</u> signals for accessing said memory means.
- 35. The <u>compression</u> apparatus of claim 34 in which said searching means includes <u>hash</u> function generation means responsive to said string code signals and to said data character signals for <u>hashing</u> a data character signal with a code signal to provide a <u>hash</u> signal, said <u>hash</u> signal providing a potential <u>address</u> signal for <u>accessing said</u> memory means.
- 37. The <u>compression</u> apparatus of claim 36 further including means for determining if all of said predetermined number of <u>hash</u> signals are unsuitable as <u>address</u> signals for accessing said memory means.
- 109. The <u>compression</u> method of claim 108 in which said searching step includes the step of <u>hashing</u> a data character signal with a code signal to provide a <u>hash</u> signal, said hash signal providing a potential <u>address</u> signal for <u>accessing said memory</u>.
- 110. The <u>compression</u> method of claim 109 in which said <u>hashing</u> step comprises <u>hashing</u> a data character signal with a code signal to provide a predetermined number of $\frac{hash}{hash}$ signals, said predetermined number of $\frac{hash}{hash}$ signals providing potential $\frac{address}{hash}$ signals for accessing said memory.
- 111. The <u>compression</u> method of claim 110 further including the step of determining if all of said predetermined number of <u>hash</u> signals are unsuitable as <u>address</u> signals for accessing said memory.
- 130. The <u>compression</u> method of claim 129 in which said searching step includes <u>hashing</u> a data character signal with a code signal to provide a <u>hash</u> signal, said <u>hash</u> signal providing a potential <u>address</u> signal for <u>accessing said memory</u>.
- 131. The <u>compression</u> method of claim 130 in which said <u>hashing</u> step includes providing a predetermined number of <u>hash</u> signals in response to a code signal and a character signal, said predetermined number of <u>hash</u> signals providing potential <u>address</u> signals for accessing said memory.
- 132. The <u>compression</u> method of claim 131 further including the step of determining if all of said predetermined number of <u>hash</u> signals are unsuitable as <u>address</u> signals for accessing said memory.

TITLE: Many-to-one mapping hash address generator

Brief Summary Paragraph Right (3):

The advantage of using a many-to-one mapping scheme in such a system is that it enables a large but sparsely populated address range to be effectively compressed into a much smaller range, thus reducing the size of the bit maps. However, as explained in those specifications, one problem with such a scheme is that the bit maps may occasionally produce spurious outputs, indicating that a data item has been tagged when in fact it has not. The number of spurious outputs may be reduced for any particular set of data items under consideration, by suitable choice of the transformation. Thus, if a first choice of transformation results in an unacceptably high number of spurious outputs, the hash coder may be modified to produce a different transformation which gives a lower number of spurious outputs.

Detailed Description Paragraph Right (13):

The indicator R is also applied to the address input of a random access memory 37 having four locations, each of which contains a <u>prime</u> number in the range 3-251. The contents of the addressed location of the memory 37 supply the hashing key K for the hash coding circuit 30.
